rban engineers learn from dance?

cities has a major impact on whether they are sustainable. d to account for 30% of energy consumption in most of the ations, so lowering the need for energy-using vehicles is essential mental impact of mobility. But as more and more people move to ink about other kinds of sustainable travel too. The ways we travel ntal health, our social lives, our access to work and culture, and ers are tasked with changing how we travel round cities through neering industry still works on the assumptions that led to the suming transport systems we have now: the emphasis placed , and quantitative data. We need radical changes, to make it and less environmentally damaging to travel around cities.

f the answers. That is not to suggest everyone should dance their lthy and happy it might make us, but rather that the techniques experiment with and design movement in dance could provide mulate new ideas in city-making. Richard Sennett, an influential ho has transformed ideas about the way cities are made, as suffered from a separation between mind and body since the ctural blueprint.

s improvised and adapted construction through their intimate d personal experience of the conditions on a site, building designs red in media technologies that detach the designer from the es they are creating. While the design practices created by these ntial for managing the technical complexity of the modern city, simplifying reality in the process.

sses the Peachtree Center in Atlanta, USA, a development typical to urban planning prevalent in the 1970s. Peachtree created a grid ded as a new pedestrian-friendly downtown for Atlanta. According use its designers had invested too much faith in computer-aided would operate. They failed to take into account that purpose-built ate in the hot sun without the protective awnings common in older energy-consuming air conditioning instead, or that its giant car coming that it would put people off getting out of their cars. What and controllable on screen has unexpected results when translated

ransport engineering, which uses models to predict and shape the ough the city. Again, these models are necessary, but they are built ws in which certain forms of efficiency and safety are considered s of the city ignored. Designs that seem logical in models appear he actual experience of their users. The guard rails that will be familiar ttempted to cross a British road, for example, were an engineering n safety based on models that prioritise the smooth flow of traffic. On ey often guide pedestrians to specific crossing points and slow down the road by using staggered access points to divide the crossing into arriageway. In doing so they make crossings feel longer, introducing rs greatly impacting those that are the least mobile, and encouraging erous crossings to get around the guard rails. These barriers don't o cross the road: they divide communities and decrease opportunities . As a result, many are now being removed, causing disruption, cost,
